

# ML PROJECT ON EXOPLANET HABITABILITY PREDICTION

By-

Name- Pranjal Sinha

Reg. no.- 12206214

Roll no.- B53

# INTRODUCTION

## *Exploring Earth-like Worlds Beyond Our Solar System*

Thousands of exoplanets have been discovered, but finding those like Earth remains a major goal.

Instead of traditional observation methods, this project uses unsupervised machine learning to group exoplanets by Earth-likeness — uncovering patterns without needing labeled data.

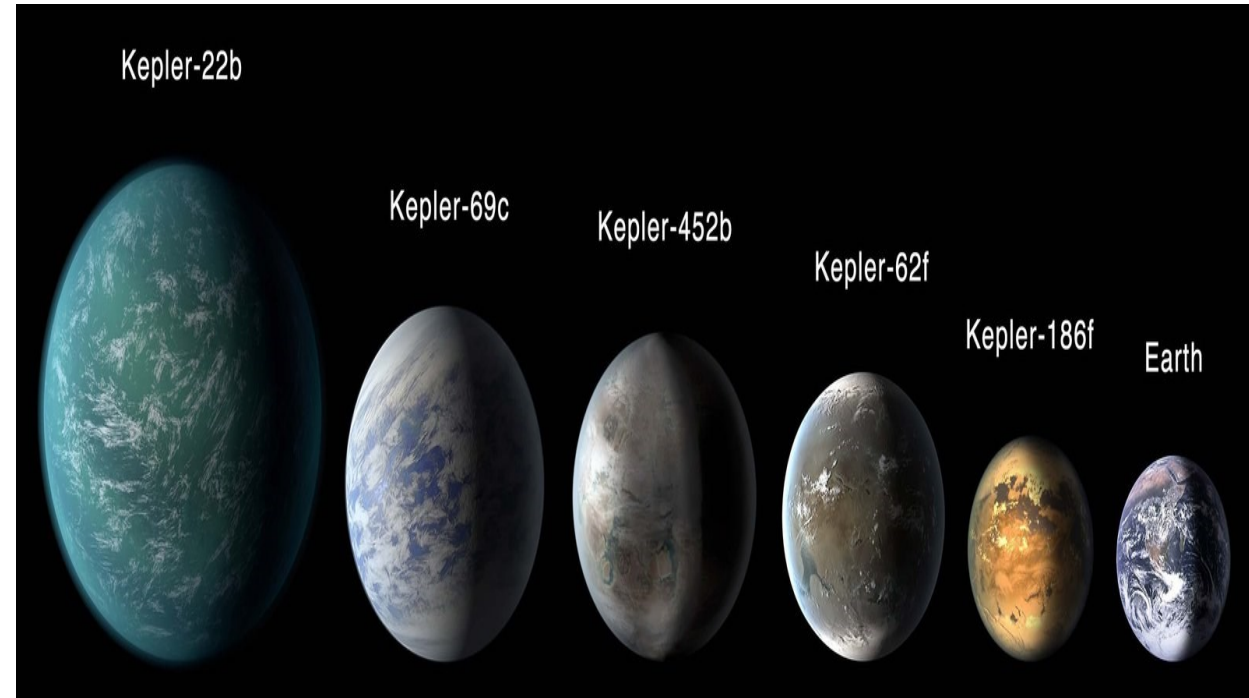

# PROBLEM STATEMENT

## *From Habitability Classification to Earth-Likeness Clustering*

The original goal was to classify exoplanets based on their habitability. However, due to the lack of labeled data indicating which exoplanets are actually habitable, we shifted to an unsupervised learning approach.

### **Our Goals:**

- Group similar exoplanets using unsupervised learning
- Measure Earth-likeness by comparing to Earth's parameters
- Build a webpage for users to input planet data and get insights

# DATASET DESCRIPTION

## *Description:*

- 5000+ confirmed exoplanets.
- Over 90 features including planetary and stellar properties.
- Key parameters include orbital period, radius, mass, equilibrium temperature, stellar temperature, and more.

## *Data Cleaning Involved:*

- Handling missing values.
- Converting units to Earth-relative scales.
- Filtering entries with critical missing data.

# KEY FEATURES USED

A variety of features were used after careful EDA and domain research:-

- 1) pl\_orbper: Orbital Period
- 2) pl\_rade: Planet Radius (Earth units)
- 3) pl\_bmasse: Planet Mass (Earth units)
- 4) pl\_eqt: Equilibrium Temperature
- 5) st\_teff: Stellar Effective Temperature
- 6) st\_rad: Stellar Radius
- 7) st\_mass: Stellar Mass
- 8) pl\_insol: Insolation Flux
- 9) pl\_orbeccen: Orbital Eccentricity

These features directly influence planetary conditions and potential for habitability.

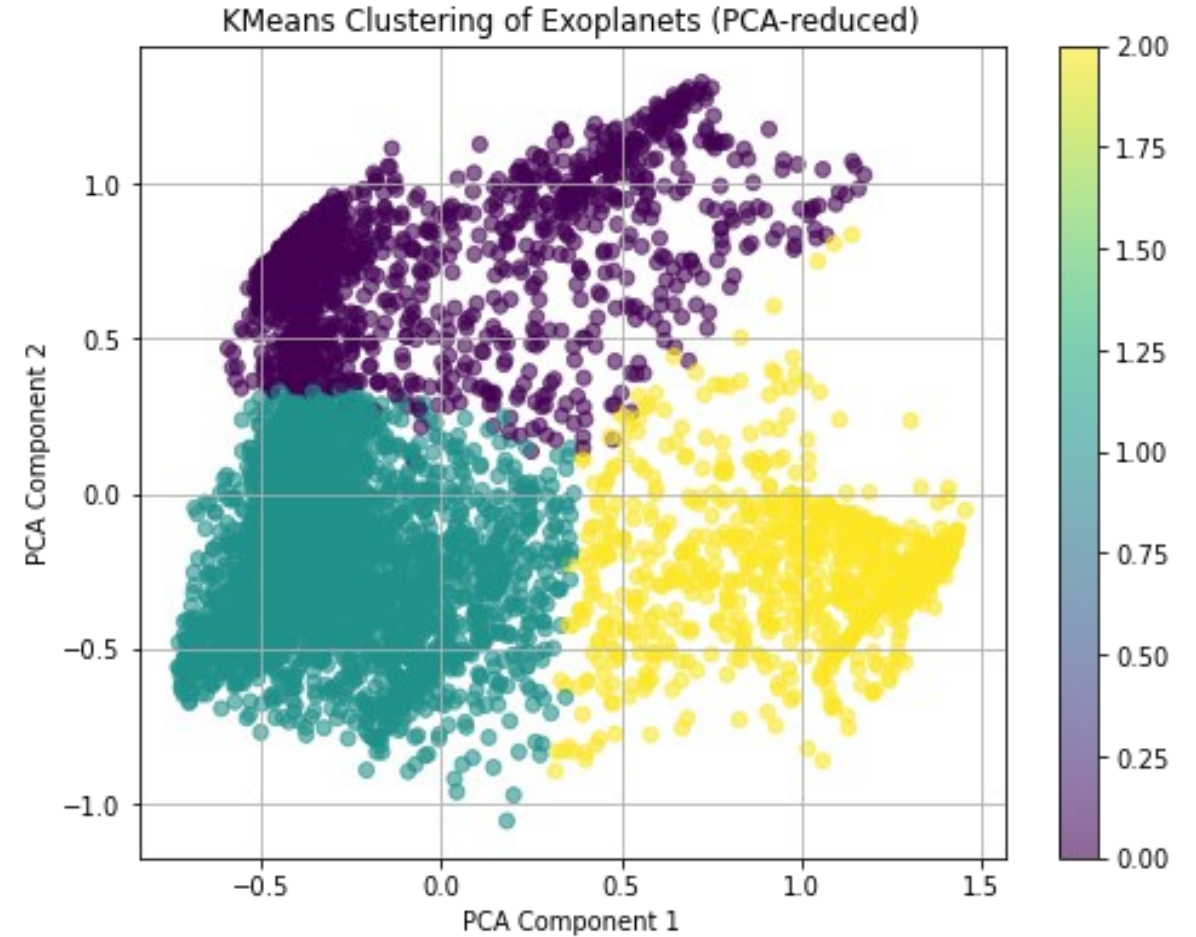

# FEATURE ENGINEERING

## Data Preparation at a Glance

- **Missing Values:** Dropped critical nulls, filled the rest with median/mode
- **Scaling:** Used StandardScaler to normalize all features
- **Dimensionality Reduction:** Applied PCA (2D) while retaining ~90% variance
- **Earth Similarity Index:** Evaluated, but skipped to maintain unsupervised integrity

# MODEL SELECTION

## Clustering Approach

- Tried **KMeans** — simple, fast, and effective
- Chose **K = 3** using the Elbow Method

## Final Clusters:

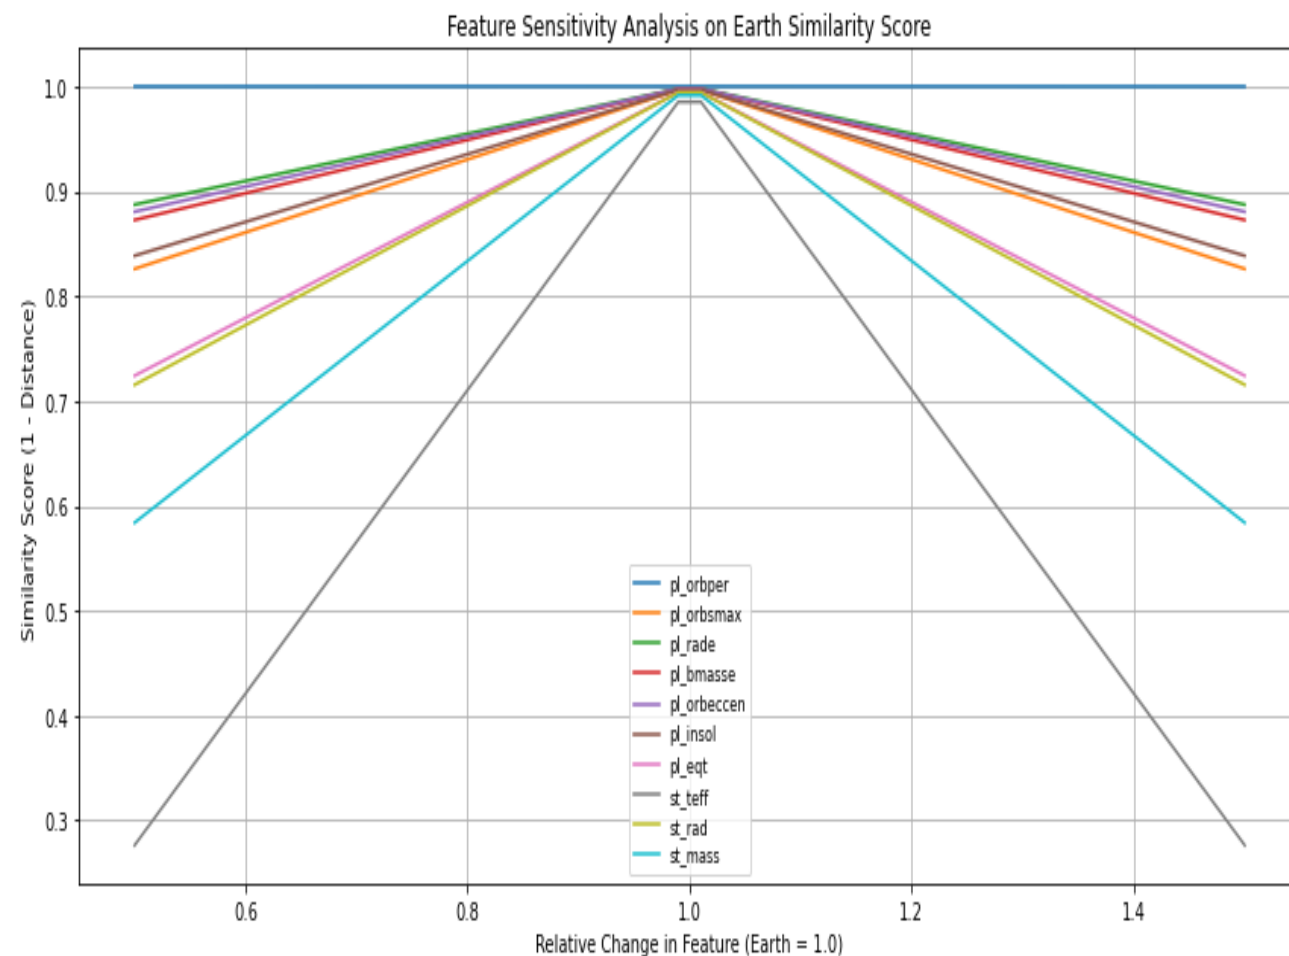

- **Cluster 0:** Earth-like
- **Cluster 1:** Intermediate
- **Cluster 2:** Unlikely to be habitable

# RESULTS

KMeans successfully divided the dataset into 3 clusters:

- Cluster 0: Close to Earth's parameters (High Habitability)
- Cluster 1: Moderately habitable planets
- Cluster 2: Hot Jupiters, rogue planets, or extreme orbits (Low Habitability)
- Visualized using PCA-reduced scatter plot. Distribution validated through cluster centers.

# WEB APPLICATION INTEGRATION

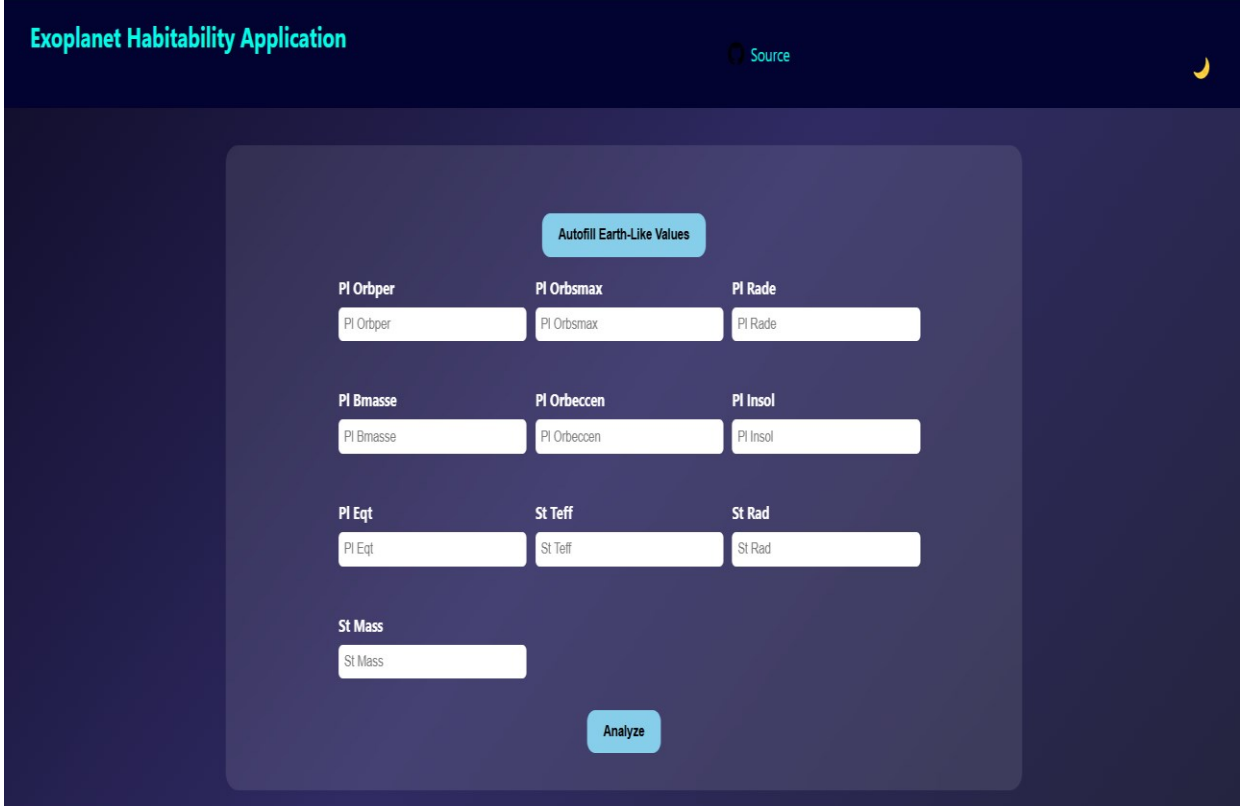

**Built with:** Python (Flask), HTML/CSS, Bootstrap

## What it does:

- Users enter planet data
- Model predicts habitability cluster

## Key Features:

- Input validation
- Real-time results
- Simple, user-friendly design

The screenshot displays the 'Exoplanet Habitability Application' interface. At the top, there is a dark blue header with the title 'Exoplanet Habitability Application' in teal on the left, a 'Source' link with a GitHub icon in the center, and a moon icon on the right. The main content area has a dark blue background with a central light blue rounded rectangle containing the input form. At the top of this form is a light blue button labeled 'Autofill Earth-Like Values'. Below this, there are nine input fields arranged in a 3x3 grid. Each field has a label above it and a text input box below it. The labels and their corresponding input boxes are: Row 1: 'Pl Orbpwr' above 'Pl Orbpwr', 'Pl Orbsmax' above 'Pl Orbsmax', and 'Pl Rade' above 'Pl Rade'. Row 2: 'Pl Bmasse' above 'Pl Bmasse', 'Pl Orbeccen' above 'Pl Orbeccen', and 'Pl Insol' above 'Pl Insol'. Row 3: 'Pl Eqt' above 'Pl Eqt', 'St Teff' above 'St Teff', and 'St Rad' above 'St Rad'. Below the grid is a single input field labeled 'St Mass' above 'St Mass'. At the bottom center of the form is a light blue button labeled 'Analyze'.

# CHALLENGES FACED

- Missing Data: Several critical columns had over 30% missing values.
- Lack of Labels: Forced us to adopt unsupervised learning.
- Feature Selection: Required astrophysical knowledge.
- Cluster Interpretation: Naming clusters without labels was subjective.
- App Integration: Linking backend ML model with a clean frontend took time.

# CONCLUSION

In conclusion, this project successfully demonstrates the use of unsupervised machine learning to assess the habitability of exoplanets based on their similarity to Earth.

By leveraging astrophysical data and clustering techniques, we shifted from a traditional classification approach to a more exploratory analysis that enables insights into planetary characteristics without requiring predefined labels.

The development of a web application further enhances accessibility and practical application of the model. This work not only deepens our understanding of exoplanetary systems but also lays the foundation for future research in astrobiology and automated planetary analysis, with potential for real-world scientific exploration.

LOVELY  
PROFESSIONAL  
UNIVERSITY

Thank you for your time and attention! I appreciate the opportunity to share my project. A special thanks to my mentors, peers, and the faculty at Lovely Professional University for their support. I hope this presentation offered valuable insights into the role of machine learning in discovering habitable worlds beyond Earth.
